CLAIMS

1   1.   A method for authenticating an external module comprising the steps of:

2   creating data K using two different schemes, at least one scheme being based

3   on the integrity of the module to be verified;

4   creating an authentication token for said module which produces K in both

5   schemes;

6   using K as created by one scheme to disrupt said module; and

7   using K as created by the other scheme to restore the module.

1   2.   The method as defined in claim 1, wherein one or more of the schemes is based

2   on RSA encryption.

1   3.   The method as defined in claim 1, wherein one or more of the schemes is based

2   on digital signets.

1   4.   The method as defined in claim 1, further comprising the step of:

2   embedding a public component of one or more of the schemes in a verification

3   code of the application.

1   5.   The method as defined in claim 1, further comprising the step of:

2   conveying private components of all schemes to a module authentication

3   authority.

1   6.   The method as defined in claim 5, wherein the creating an authentication token

2   step is automated by providing developers of the external module access to a Web site

3   which allows them to submit the hash of their module and to retrieve the authentication

4   token.

1   7.   The method as defined in claim 1, wherein the authentication token is embedded

2   in the external module as long as the external module itself remains functional.

1   8.   The method as defined in claim 7, where the embedding is realized by adding an

2   additional data section to a DLL in Portable Executable (PE) format.

1   9.   The method as defined in claim 1, wherein the authentication token is external to

2   the external module.

1   10.   The method as defined in claim 1, wherein said scheme depending on code

2   integrity is independent of a location of the external module in memory.

1   11.   The method as defined in claim 10, wherein location independence is achieved

2   by locating and reading the external module's image on a disk.

1   12.   The method as defined in claim 10, wherein location independence is achieved

2   by using a canonical hash.

SOM9-2000-0012-US1   15

1   13.   A method for secure authentication of external modules on an entity comprising

2   the steps of:

3   loading an external module into memory; and

4   beginning a STOMPing process by decrypting a number of pseudo-random bytes

5   that are part of an authentication token using a public security code of a public and

6   private component pair security code.

1   14.   The method as defined in claim 13, wherein the public and private components of

2   the security code comprise security codes selected from a group of security codes of: a

3   signet pair and an RSA pair.

1   15.   The method as defined in claim 13, further comprising the step of:

2   XORing the decrypted pseudo-random bytes with the external module making

3   the external module unusable.

1   16.   The method as defined in claim 15, further comprising the step of:

2   performing a signet extrication process to generate extrication data by using the

3   hash of the external module to begin an UNSTOMPing process.

1   17.   The method as defined in claim 16, further comprising the step of:

2   using the extrication data to generate another stream of pseudo-random bytes.

1   18.   The method as defined in claim 17, further comprising the step of:

2   XORing the another stream of pseudo-random bytes with the unusable external

3   module thereby making the unusable external module usable in the event there has

4   been no illicit patching of the external module and maintaining the unusable external

5   module unusable in the event that the external module has been illicitly patched such

6   that an application or program that is accessing the module fails to operate.

1 19. The method as defined in claim 18, further comprising the step of:

2   re-authenticating the external module by periodically performing the STOMP and

3 UNSTOMPing process multiple times while interacting with the external module.

1 20. The method as defined in claim 18, further comprising the step of:

2 performing run time checks to make sure that function calls to the external module are

3 not intercepted by an attacker.

1 21.   A computer readable medium comprising instructions for secure authentication of
2 external modules on an entity comprising the instructions of:
3   loading an external module into memory; and
4   beginning a STOMPing process by decrypting a number of pseudo-random bytes
5 that are part of an authentication token using a public security code of a public and
6 private component pair security code.

1 22.   The computer readable medium as defined in claim 21 wherein the public and
2 private components of the security code comprise security codes selected from a group
3 of security codes of: a signet pair and an RSA pair.

4　23.　The computer readable medium as defined in claim 21 further comprising the

5　instruction of:

6　　　　XORing the decrypted pseudo-random bytes with the external module making

7　the external module unusable.

1　24.　The computer readable medium as defined in claim 23 further comprising the

2　instruction of:

3　　　　performing a signet extrication process to generate extrication data by using the

4　hash of the external module to begin an UNSTOMPing process.

1　25.　The computer readable medium as defined in claim 24 further comprising the

2　instruction of:

3　　　　using the extrication data to generate another stream of pseudo-random bytes.

1　26.　The computer readable medium as defined in claim 25 further comprising the

2　instruction of:

3　　　　XORing the another stream of pseudo-random bytes with the unusable external

4　module thereby making the unusable external module usable in the event there has

5　been no illicit patching of the external module and maintaining the unusable external

6　module unusable in the event that the external module has been illicitly patched such

7　that an application or program that is accessing the module fails to operate.

1　27.　A system for secure authentication of external modules on an entity comprising

2　the units of:

3　　　　a loader unit for loading an external module into memory; and beginning a

4　STOMPing process by

5　　　　a decryption unit for decrypting a number of pseudo-random bytes that are part

6　of an authentication token using a public security code of a public and private

7　component pair security code.
